- Chapter 13 - WorkforceIQ Metric Glossary
- Chapter 14 - Frequently Asked Questions and Troubleshooting

Chapter 1 - Welcome to WorkforceIQ

WorkforceIQ is a local operational intelligence dashboard that turns staffing, inventory, receipts, closures, SLA, production, and FTE information into practical decision support. Instead of asking users to scan a wide spreadsheet and infer the story manually, WorkforceIQ organizes the same operational information into health indicators, drill-down views, and short-range directional forecasts.

The dashboard is designed for operational leadership, department managers, Workforce Management personnel, business analysts, operational associates, and executive stakeholders. It helps these users quickly understand where work is moving, where service-level pressure exists, whether productive capacity appears sufficient, and which areas may need further investigation.

WorkforceIQ does not replace operational judgment. It helps focus attention by translating reporting data into clear signals, explanations, and planning scenarios.

The primary business questions WorkforceIQ helps answer are:

- Are we meeting operational expectations?
- Is backlog increasing or decreasing?
- Are receipts and closures balanced?
- Do we have sufficient productive capacity to keep pace with incoming work?
- Which business units or work categories need attention?
- What operational signals may be contributing to pressure?
- What could happen if current trends continue?

The dashboard has six main sections:

Section	Purpose
Pulse	Executive landing page for overall health, ranked attention areas, and business-unit status.
Flow	Shows how incoming work, completed work, and inventory/backlog are moving.
Staffing	Explains department capacity, FTE, productivity, and workload pressure areas.
Forecast	Projects receipts, closures, inventory, out-of-standard work, SLA, and scenario impacts.
Intelligence	Shows early warnings and likely operational drivers for the selected context.
Detail	Displays the underlying operational actuals by business unit and work category.

Chapter 2 - Getting Started and Navigation

Open WorkforceIQ by opening `dashboard.html` in the WorkforceIQ project folder. The dashboard reads the generated local data file, `data/dashboard-data.js`. No server is required.

When the dashboard first loads, users see a short loading screen, then the Pulse view. The default reporting period is usually the latest full operational period. This matters because a newer reporting period can exist with inventory or SLA data but without complete receipts, closures, production, and FTE information.

Annotated overview: 1 data freshness, 2 executive KPI cards, 3 filters, 4 dashboard tabs, 5 intelligence rail.

Control	How to use it
Dashboard View	Changes the primary section: Pulse, Flow, Staffing, Forecast, Intelligence, or Detail.
Business Unit	Filters the dashboard to All business units or a selected unit such as CB, CGS, or GB.
Work Category	Filters to All work categories or a specific work type such as Disputes or Correspondence.
Period	Changes the reporting month displayed in the dashboard.
Reset	Returns the dashboard to Pulse, All business units, All work categories, and the default full operational period.
Refresh	Rerenders the currently loaded local dashboard data. It does not import a new source report.
Guide Me	Opens a question-based navigation helper.
Presentation Mode	Changes the display style for meeting use. It does not change data.

Last Refreshed is when the dashboard data file was generated. **Latest Source Period** is the most recent reporting period available in the source data. **Latest Full Operational Period** is the most recent period with the operational fields needed for flow, staffing, and capacity analysis.

In the current data, the latest source period is 2026-09, while the latest full operational period is 2026-08. That is why the dashboard may default to 2026-08 for operational analysis.

Many dashboard elements are clickable. KPI cards navigate to related sections. Bar rows and table rows open detail views. Information icons show short explanations when hovered. Forecast rows and tiles open a calculation explanation modal.

Chapter 3 - Understanding the Executive KPI Cards

The five cards across the top summarize the selected operational context. They update whenever filters change.

Card	What it means	Click behavior
Capacity	Shows whether department-level productive capacity appears sufficient, short, or surplus based on receipts, closures, and FTE.	Opens Staffing.
SLA Health	Shows selected-context SLA against the 90% target. The dashboard recalculates aggregate SLA from in-standard work divided by starting inventory.	Opens Detail.
Backlog	Shows whether closures exceeded receipts. Positive throughput means the operation may burn down backlog; negative throughput means backlog pressure is growing.	Opens Flow.
Operational Health	Counts critical, at-risk, and watch areas in the selected context. If none are flagged, it reports that all areas are healthy.	Opens Pulse.
Outlook	Summarizes the next forecast direction as Improving, Stable, Deteriorating, or Directional with a confidence label.	Opens Forecast.

Example: if the Backlog card shows an upward value labeled Growing, incoming work exceeded completed work. A manager should open Flow to compare receipts and closures, then open Staffing to see whether department capacity is contributing to the pressure.

Example: if Capacity shows a shortfall, that estimate answers whether the operation appears to have enough productive capacity to keep pace with incoming receipts. It does not automatically mean the same amount of staffing would eliminate all accumulated backlog.

Chapter 4 - Workforce Pulse

Pulse is the primary landing page. It is built for the question, **Where should I focus my attention today?**

Pulse shows selected-context SLA, starting inventory, a count of flagged areas, a ranked attention list, and enterprise health by business unit. Rows marked Critical, At Risk, or Watch are shown first. If nothing is flagged, Pulse says the selected context is healthy instead of inventing a problem.

- Use Pulse before meetings to identify the highest-risk business unit or work category.
- Click an attention row to open the detail modal and review source SLA, calculated SLA, inventory, out-of-standard work, and throughput balance.
- Use the Business Unit health bars to move quickly from an enterprise view into a specific unit.

Practical example: a department manager preparing for a leadership meeting starts in Pulse with Business Unit set to All and Work Category set to All. If GB Disputes appears as the highest-risk area, the manager clicks it, reviews the operational snapshot, then checks Flow and Staffing to determine whether pressure is related to incoming demand, output, inventory, or capacity.

Chapter 5 - Flow: Understanding Workload Movement

Flow explains the relationship between incoming work, completed work, and existing inventory. It is the best section for understanding whether the operation is keeping pace with demand.

Term	Plain-English meaning
------	-----------------------

Receipts	Incoming work received during the reporting period.
Closures	Work completed or closed during the reporting period.
Starting Inventory	Work/backlog present at the start of the reporting period.
Throughput Balance	Closures minus receipts. Positive is favorable; negative means incoming work exceeded completed work.
Backlog Growth	Occurs when receipts are greater than closures.
Backlog Burn-Down	Occurs when closures are greater than receipts.
Burn-Down Runway	A run-rate estimate showing where inventory may go if the current throughput rate continues.

Throughput Balance = Closures - Receipts. A positive result means closures exceeded incoming work. A negative result means incoming work exceeded closures.

Numerical example: if a team receives 1,000 items and closes 1,200 items, throughput balance is +200. Existing backlog has an opportunity to decline. If the team receives 1,200 items and closes 1,000 items, throughput balance is -200. Backlog pressure is increasing.

The Flow tab includes a throughput callout, an inventory burn-down runway chart, timing estimates for 10% and 25% inventory reduction, a receipts-versus-closures comparison, and an inventory position view.

Chapter 6 - Staffing and Productive Capacity

The Staffing section helps users evaluate whether available productive capacity appears sufficient to keep pace with incoming workload. It uses available department-level staffing information and observed productivity.

Metric	How to read it
Department FTE	Available staffing capacity for the department/business unit in the selected period.
Average Daily Receipts	Average amount of incoming work per day.
Average Daily Production	Average amount of completed production per day.
Production-to-Receipts Ratio	Daily production divided by daily receipts. Above 100% means production is ahead of incoming volume.
Closures per FTE	Monthly closures divided by FTE. Used to estimate productive capacity.
Capacity Shortfall	Estimated additional FTE-equivalent productive capacity needed to keep pace with current receipts.
Capacity Surplus	Estimated FTE-equivalent capacity above what is needed to keep pace with current receipts.
Workload Pressure Areas	Specific work categories ranked by operational risk; these provide workload context, not exact staffing allocation proof.

Important: WorkforceIQ does not assume exact FTE allocation by work category unless the source data explicitly supports it. Staffing scenarios should be read at the department/business-unit level.

Capacity to keep pace and capacity to reduce backlog are different questions. A department may have enough capacity to close the same amount of work it receives this month, while still carrying old backlog. Reducing accumulated backlog requires closures to exceed receipts for a sustained period.

Practical example: if Staffing shows a 2.5 FTE-equivalent shortfall, the manager should read that as a keep-pace signal. It means observed productivity suggests more capacity would be needed to match incoming receipts. The manager should then look at Flow to see whether backlog is growing and Forecast to test whether additional FTE could improve future inventory and SLA.

Chapter 7 - Forecast: Understanding What May Happen Next

Forecast is a directional planning view. It projects what may happen to receipts, closures, inventory, out-of-standard work, and SLA if recent operational trends continue. It is designed to support planning conversations, not to guarantee outcomes.

Annotated forecast view: 1 select a specific business unit and work category, 2 adjust temporary scenario controls, 3 read receipts/closures/inventory lines, 4 review crossover and goal timing, 5 inspect the forecast table.

Receipts are projected incoming work during each future period. **Closures** are projected completed work during each future period. **Inventory** is the projected backlog level after receipts and closures interact.

Next Inventory = Current Inventory + Receipts - Closures. If closures exceed receipts, inventory can decline. If receipts exceed closures, inventory can increase.

Crossover means projected closures begin exceeding projected receipts. The dashboard distinguishes three conditions:

- Positive throughput now: closures already exceed receipts in the current or baseline context.
- Future crossover: closures are projected to exceed receipts in a future displayed month.
- No Crossover Expected: projected closures remain below projected receipts throughout the forecast horizon.

The Forecast table displays Current, Month +1, Month +2, and Month +3. Each row includes projected receipts, closures, balance, inventory, out-of-standard work, expected SLA, and confidence. Clicking a row opens a modal explaining the math for projected balance, inventory roll-forward, and expected SLA.

Forecast confidence considers available history, missing recent fields, recent SLA volatility, and forecast horizon. Current forecasts are directional because the available history is limited. The dashboard does not present these outputs as trained machine-learning predictions.

Numerical example: if current inventory is 5,000, projected receipts are 1,200, and projected closures are 1,500, next inventory is 4,700. Because closures exceed receipts by 300, backlog declines. If projected receipts are 1,500 and closures are 1,200, next inventory is 5,300 and backlog grows.

Chapter 8 - Interactive What-If Forecasting

The Forecast tab includes temporary scenario controls. These controls let users test planning assumptions without changing historical data or the generated dashboard data file.

- 1 Select a specific Business Unit and Work Category. Forecast scenarios do not run from an All/All context.
- 2 Open the Forecast view.
- 3 Use the Staffing control to increase or decrease department FTE.
- 4 Use the Workload buttons to model incoming receipts at -10%, current, or +10%.
- 5 Use the Productivity buttons to model closures at -5%, current, or +5%.
- 6 Optionally enter a Backlog Goal to test when inventory might reach a target level.
- 7 Review changes to projected receipts, closures, throughput balance, inventory, and expected SLA.
- 8 Use Reset To Baseline Forecast to return to the original forecast assumptions.

A baseline forecast is the dashboard's current projection before the user changes scenario controls. A what-if scenario applies temporary planning assumptions on top of that baseline.

Worked example: leadership asks what could happen if incoming workload increases by 10% while department staffing increases by three FTE. Select the department and work category, open Forecast, increase the Staffing input by 3, choose +10% under Workload, and keep Productivity at Current unless a productivity change is also expected. Then compare projected closures, throughput balance, ending inventory, and expected SLA against the baseline. If throughput remains negative, additional staffing may not be enough by itself. If throughput turns positive, the forecast may show crossover or a clearer backlog burn-down path.

Scenario adjustments are temporary. They do not update historical actuals, source reports, source-records.json, or dashboard-data.js.

Chapter 9 - Intelligence: Understanding Operational Drivers

The Intelligence section helps users understand why an area may be under pressure. It displays early-warning indicators and likely drivers for the selected context.

Early Warnings appear when SLA may still be meeting target but multiple leading indicators suggest pressure is forming. Examples include rising receipts, declining closures, positive receipt/closure gaps, production below receipts, increasing out-of-standard work, or workload growing faster than FTE.

Primary Drivers are formula-based operational signals. They may include receipt growth, closure decline, workload pressure, out-of-standard movement, flow gap, and reroutes. Clicking a driver opens a modal that explains the definition, formula, raw value, normalized displayed score, and source inputs.

A driver is a signal, not proof of root cause. Use Intelligence to focus investigation, then confirm causes with operational context, staffing knowledge, process details, and source-system review.

Example: if Intelligence shows Receipt Growth and Flow Gap as the strongest signals, a manager might investigate volume spikes, upstream routing, work mix, and whether staffing or productivity changes are needed. If OOS Movement dominates, the investigation may focus on aging inventory and SLA recovery actions.

Chapter 10 - Detail: Reviewing Actual Operational Information

Detail shows the actual operational rows for the selected reporting period and filters. It is the best place to inspect the underlying metrics behind the higher-level cards and charts.

Displayed field	Meaning
Business Unit	Operational unit such as CB, CGS, or GB.
Work Category	Type of work such as Disputes, Correspondence, Cash Posting, Host, or Validation/Adjustments.
Operational Status	Current health classification: Meeting Target, Watch, At Risk, Critical, or No Data.
Source SLA	SLA value supplied by the source report.
Calculated SLA	In-standard inventory divided by starting inventory.
Inventory	Starting inventory/backlog for the period.
Out of Standard	Inventory that is outside standard.
Receipts	Incoming work for the period.
Closures	Completed work for the period.
Balance	Throughput balance: closures minus receipts.
FTE	Available staffing information from the source.

Detail contains historical actuals for the selected period. Forecast contains future directional estimates. Do not compare a forecasted future value as if it were an actual source result.

Clicking a Detail row opens an operational snapshot and intelligence brief for that business unit/work category.

Chapter 11 - Understanding the Intelligence Rail

The Intelligence Rail is the right-side contextual panel. It updates based on the selected Business Unit, Work Category, Period, and dashboard context.

Rail section	How to use it
Current State	Summarizes the selected context and its status.
Why It Matters	Lists the evidence supporting the current operational interpretation.
Primary Driver	Calls out the most direct signal, such as incoming work exceeding closures.
Early Warning	Shows whether leading indicators are active.
Outlook	Shows the next projected SLA when forecast data is available, otherwise the simple trend continuation summary.
Recommended Lever	Suggests the type of operational lever to consider, such as capacity, throughput, or backlog reduction.

Use the rail as a companion to the main chart. For example, Flow may show backlog growing, while the rail explains the primary driver and whether the selected area also has a capacity shortfall or early warning signal.

Chapter 12 - Practical WorkforceIQ Walkthroughs

Use these task-based walkthroughs as training exercises or daily operating routines.

Business question	Recommended workflow
-------------------	----------------------

A. My department's SLA is declining.	Open Pulse, filter to the department, review attention rows, then open Detail for Source SLA and Calculated SLA. Check Intelligence for likely drivers and Flow for backlog direction.
B. Incoming work is exceeding closures.	Open Flow. Review Throughput Balance, Receipts In, Closures Out, and burn-down runway. A negative balance means backlog pressure is increasing.
C. I need to understand whether staffing is sufficient.	Open Staffing. Review department FTE, production-to-receipts ratio, and capacity shortfall/surplus. Then compare Flow to see whether backlog is actually burning down.
D. I want to identify which area requires attention.	Start in Pulse with All filters. Review Attention Required and Enterprise Health. Click the highest-risk row for a detail modal.
E. I want projected backlog for the next three months.	Select a specific Business Unit and Work Category, then open Forecast. Review inventory line, forecast table, crossover, and backlog goal tile.
F. Leadership asks what additional staffing could change.	Open Forecast for a specific context. Increase Staffing/FTE, then compare projected closures, balance, inventory, and expected SLA against baseline.
G. I need a meeting summary.	Use Pulse for health, Flow for backlog direction, Staffing for capacity, Forecast for outlook, and the Intelligence Rail for a concise explanation.

For every walkthrough, pay attention to whether you are viewing all business units or a filtered context. Filters change the meaning of every card, chart, table, and rail statement.

Chapter 13 - WorkforceIQ Metric Glossary

Metric	Definition	Calculation	Interpretation / limitation
Backlog	Work still present in inventory.	Often represented by Starting Inventory or projected Inventory.	A backlog can exist even when capacity is currently sufficient.
Backlog Burn-Down	A condition where closures exceed receipts.	Closures - Receipts is positive.	Must persist to reduce accumulated inventory.
Calculated SLA	SLA calculated by WorkforceIQ from source counts.	In Standard / Starting Inventory.	May differ from Source SLA if source definitions differ.
Capacity Shortfall	Estimated FTE-equivalent productive capacity needed to keep pace.	Required FTE - Current FTE.	Directional, department-level estimate.
Capacity Surplus	Estimated productive capacity above what is needed to keep pace.	Negative capacity gap shown as surplus.	Does not automatically mean backlog is eliminated.
Closures	Work completed during the period.	Source metric.	Compared with receipts to determine flow.
Crossover	Future point where projected closures exceed receipts.	First forecast period with positive throughput balance.	No crossover means closures stay below receipts within the horizon.
Expected SLA	Forecasted future SLA.	1 - projected OOS / projected inventory.	Directional estimate.
Forecast Confidence	Label describing how much support the forecast has.	Considers history, missing data, volatility, and horizon.	Low confidence does not mean useless; it means treat as directional.
FTE	Staffing level from the source data.	Source metric.	Read as department-level unless source proves finer allocation.

Inventory	Work/backlog count.	Source actual or forecast projection.	In Forecast, inventory is rolled forward from receipts and closures.
OOS / Out of Standard	Inventory outside standard.	Source metric.	Higher OOS usually increases SLA pressure.
Production-to-Receipts Ratio	Daily production compared with incoming daily receipts.	Average Daily Production / Average Daily Receipts.	Above 100% means production is ahead of incoming volume.
Receipts	Incoming work during the period.	Source metric.	When receipts exceed closures, pressure grows.
SLA	Service-level performance.	Source SLA or calculated SLA.	Dashboard target is 90%.
Throughput Balance	Whether the operation completed more work than it received.	Closures - Receipts.	Positive is favorable; negative means incoming work exceeded closures.

Chapter 14 - Frequently Asked Questions and Troubleshooting

Question	Answer
Why am I seeing N/A?	The selected period or context does not have the source fields needed for that metric, or the calculation would require division by zero.
Why does the dashboard show an earlier reporting month?	The latest source period is 2026-09, but the latest full operational period is 2026-08. WorkforceIQ defaults to the complete operational period for views that require receipts, closures, production, or FTE.
What does partial data mean?	A period has some source information but is missing operational fields such as receipts, closures, FTE, average daily receipts, or average daily production.
Why do Forecast and Detail display different numbers?	Detail shows actual historical values for the selected period. Forecast shows directional projected future values and scenario outputs.
What does limited forecast confidence mean?	The dashboard has limited history, missing recent fields, or volatility. Treat the forecast as a planning signal, not a guaranteed result.
Why is no crossover expected?	Projected closures do not exceed projected receipts within the displayed forecast horizon.
What does a negative Throughput Balance mean?	Incoming work exceeded completed work. Backlog pressure is increasing unless throughput improves.
Why can capacity appear sufficient while backlog still exists?	Capacity may be enough to keep pace with current receipts, but reducing existing backlog requires closures to exceed receipts.
Are what-if changes permanent?	No. Scenario changes are temporary browser-side assumptions and do not modify source data.
Does Refresh retrieve new source data?	No. The Refresh button rerenders the currently loaded dashboard data. To load new source data, run the dashboard update script.
How do I return to the original forecast?	Use Reset To Baseline Forecast in the Forecast tab.
